

Solution for prefabricated steel floors

In principle, prefabricated steel floors do not bear large loads like the ground so the floor does not have some kind of foundation structure. Industrial floors are limited between two spaces - the upper and lower floors so the industrial floor structure is often placed in relation to the upper floor and the double floor of the upper floor. In the case of prefabricated floors, it is necessary to arrange machines, heavy equipment and forces acting on different bearing structures, we should use the floor support structure to separate from the bearing frame system.
